Assignment 0x01

Frank Kaiser – 1742945, Jan Martin – 1796943

November 19, 2017

Contents

1	Task 1: Account Recovery	2
2	Task 2: Public-Key Authentication in SSH 2.1 GNU/Linux 2.2 Windows	
3	Task 3: Buffers in C: The Vigenre Cipher	5
4	Task 4: Memory Management on the Stack	7

1 Task 1: Account Recovery

Snow is white.

Figure 1: ssh-keygen

```
[aro@arch-aro -]s ssh-copy-id kaiser@88.99.184.129
/usr/bin/ssh-copy-id- Nibro: attempting to log in with the new key(s), to filter out any that are already installed
/usr/bin/ssh-copy-id: IMFO: 2 key(s) remain to be installed -- if you are prompted now it is to install the new keys
kaiser@88.99.184.129's password:

Number of key(s) added: 2

Now try logging into the machine, with: "ssh 'kaiser@88.99.184.129'"
and check to make sure that only the key(s) you wanted were added.
```

Figure 2: save public key on server

2 Task 2: Public-Key Authentication in SSH

2.1 GNU/Linux

To generate the ssh-key pair I used the command ssh-keygen which generates by default a 2048 bit long rsa key.

To copy the key on the server ssh-copy-id user@88.99.184.129 was used. Since I already had a public key for another server and the exercise was to create one, both keys got uploaded to the server as seen in the picture 2.

The following log-in worked without the user password for the server. Only the optional password for the private ssh key was required. The keys on the server are stored in ~/.ssh/authorized_keys. See figure 3

```
[arc@arch-arc =]s ssh kaiser@88.99.184.129
Linux psi-introsp 4.9.0-4-am664 #1 SMP Debian 4.9.51-1 (2017-09-28) x86_64

Figure 3: location of keys on server

Figure 4: location of keys on local machine

```
martin@psi-introsp:~/.ssh$ ls
authorized_keys known hosts
martin@psi-introsp:~/.ssh$ ls -1
total 8
-rw-r--r- 1 martin martin 398 Nov 17 21:22 authorized_keys
-rw-r--r- 1 martin martin 215 Nov 6 18:00 known_hosts
martin@psi-introsp:~/.ssh$
```

Figure 5: permission check

The ssh-keys on your local machine are by default stored in ~/.ssh/id_rsa.pub for the public part and the private one in ~/.ssh/id_rsa. (Provided you did create a rsa key) See figure 4.

2.2 Windows

On a windows machine the same tools from openSSH were not available. That's why the procedure was a little bit different. Here PuTTY was used.

To generate the key the tool putty-gen was used. Then we logged into the server via ssh and created the file authorized_keys in ~/.ssh/ and pasted the key into it using nano. Lastly, we checked that only we have write access to the file by ls -1

In figure 6 you can see the successful login by using the ssh-key pair.

```
login as: martin
Authenticating with public key "rsa-key-20171117"
Passphrase for key "rsa-key-20171117":
Linux psi-introsp 4.9.0-4-amd64  $1 SMP Debian 4.9.51-1 (2017-09-28) x86_64
Last login: Fri Nov 17 20:55:56 2017 from 185.53.42.56
martin@psi-introsp:~$ [
```

Figure 6: windows ssh-key login

3 Task 3: Buffers in C: The Vigenre Cipher

```
The source code for the exercise can be found in the following file: Vigenere Cipher
   To compile: gcc -Wall vigenere_cipher.c -o "output-name" Optional flag:
-DDEBUG
   Below is the source code readable:
#include <ctype.h>
#include <stdio.h>
#include <string.h>
int getRotation(char c) {
  /*According to ascii 'A' transfers to 65
  and Z to 90. By subtracting 65 of the char we get
  the rotation. */
  return c - 65;
}
int main(int argc, char *argv[]) {
  char key [256];
  char word [256];
  printf("Type_in_the_key\n");
  fgets (key, sizeof (key), stdin);
  printf("What_do_you_want_to_encrypt?\n");
  fgets (word, sizeof (word), stdin);
  // Number of char that were not uppercase
  int cntSkipped = 0;
  // length of the key - 1 to know when to start from 0
  int \text{ keyLength} = strlen(\text{key}) - 1; // remove \setminus n
                                      // index of the key word
  int keyPosition = 0;
  for (int i = 0; i < strlen(word); i++) {
                 /* Set keyPosition to 0 when end of key is reached
                  i is substracted by the number of skipped chars
                  so the % operator works as intended */
    if ((i > 0) & ((i - cntSkipped) \% keyLength == 0)) {
       keyPosition = 0;
    }
    // ignore lowercases and whitespaces
    if (!isupper(word[i])) {
       cntSkipped++;
       continue;
```

```
int rotation = getRotation(key[keyPosition]);
    keyPosition++;

#ifdef DEBUG
        printf("%i_", rotation);
#endif

    word[i] = ((word[i] - 'A' + rotation) % 26) + 'A';
}
    printf("%s", word);

return 0;
}
```

4 Task 4: Memory Management on the Stack

To get the Success! message you have to do a buffer overflow by giving more than 16 characters as input string. After that you can put input chars on the stack. You can set two variables at once, because memory was allocated for variables 'myvalue' and 'mystring'. The stack is first in, last out, i.e. the first element put into it, will be the last one read. Because of this you have to put in the chars in reverse order. The resulting command looks like this:

echo -e "0000000000000000\xef\xbe\xad\xde" | ./memory

```
kaiser@psi-introsp:~$ echo -e "0000000000000000\xef\xbe\xad\xde" | ./memory
Success!
Segmentation fault
kaiser@psi-introsp:~$
```

Figure 7: Successful input
